Evaluation method

In terms of both requirements and design quality, efficiency and cost are presented separately.

Evaluation tasks and samples

Each model is evaluated around the unified design tasks, covering five scenarios: Web application, mobile app, desktop client, board and management background, official website and landing page. We evaluate the performance of the model in the actual prototype generation task, not the general ability.

Page rendering check

Before scoring, check whether the product can be opened normally as a web page, including whether there is a blank page, truncated content or fatal running error. Products that cannot be rendered are counted as zero points, and the results will not be replaced through the make-up test. The page can be opened only to enter the basis of the follow-up evaluation, which does not mean that the requirements have been completed, nor does it mean that the product has reached the deliverable standard.

Requirements for completion and design quality

The full score of a single product is 100, which consists of two parts: requirement completion and design quality. The requirement completion score is 30 points: according to the specific requirements of each task, check the page and module, necessary content, interface status and interaction behavior one by one, and score according to completion, partial completion or incompleteness. Design quality accounts for 70 points: from the five dimensions of layout and readability, information hierarchy, style and task matching, color matching and contrast, picture adaptation and content relevance, each dimension is also distinguished between standard, partial standard and non-standard.

Evaluation average score and deliverability rate

The evaluation average score is the arithmetic average of the total score of all rated products in the model, which is used to compare the overall performance. If a single product reaches 80 points, it is considered deliverable in this evaluation; the deliverable rate is the proportion of the rated products that meet this standard, which is used to observe the ability of the model to stabilize the output of qualified results. The "deliverable" here refers to meeting the prototype quality standards of this evaluation, which is not equivalent to the one that can be directly used in the production environment.

Efficiency and cost

In addition to the score, we separately count efficiency indicators such as completion time consumption, cache hit rate, input and output Token usage, and the number of tool calls, and adopt the actual average. The cost of a single portion is estimated according to the recorded Token usage according to the standard input, output and cache reading unit price, and then calculates the average. The result is used to compare resource consumption and does not represent the actual bill, nor does it include unrecorded additional costs. Efficiency and cost are not included in the total evaluation score; switching the selection preference only changes the recommended ranking, not the original evaluation score of the model.
